

Language-universal and script-specific factors in the recognition of letters in visual crowding:

The effects of lexicality, hemifield, and transitional probabilities in a right-to-left script

Adi Shechter, Sivan Medina, David L. Share, Amit Yashar

NOVEMBER 2023

Crowding

- Crowding refers to the failure to identify a peripheral item in clutter (Bouma, 1970).
- Mostly pronounced at the visual periphery.

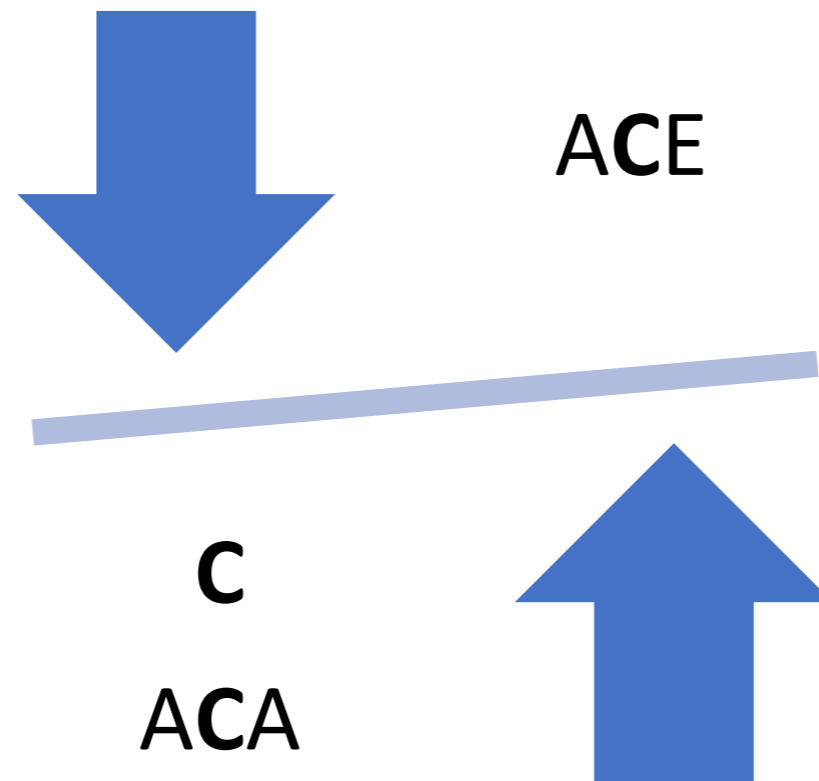

Crowding and reading

- The visual periphery plays an important role in preprocessing upcoming words during reading (Schotter et al., 2012).
- Crowding sets significant constraints on the visual-orthographic processes involved in reading (Grainger et al., 2016).
- Whether sequential probabilities of letters influences crowding interference?
- We address this issue in the context of letter recognition.

Introduction

Central vision		Visual periphery	
Word superiority effect	Word lexicality effect	Word superiority effect	Word lexicality effect
☑	☑		
(e.g., McClelland & Rumelhart, 1981)

Sub-lexical information and letter identification

- Words and pseudowords differ in their probabilities of the word-internal sequence of letters.
- Certain bigrams and trigrams have higher probabilities than others.
- No studies have yet directly investigated the influence of transitional probability on letter recognition in print.

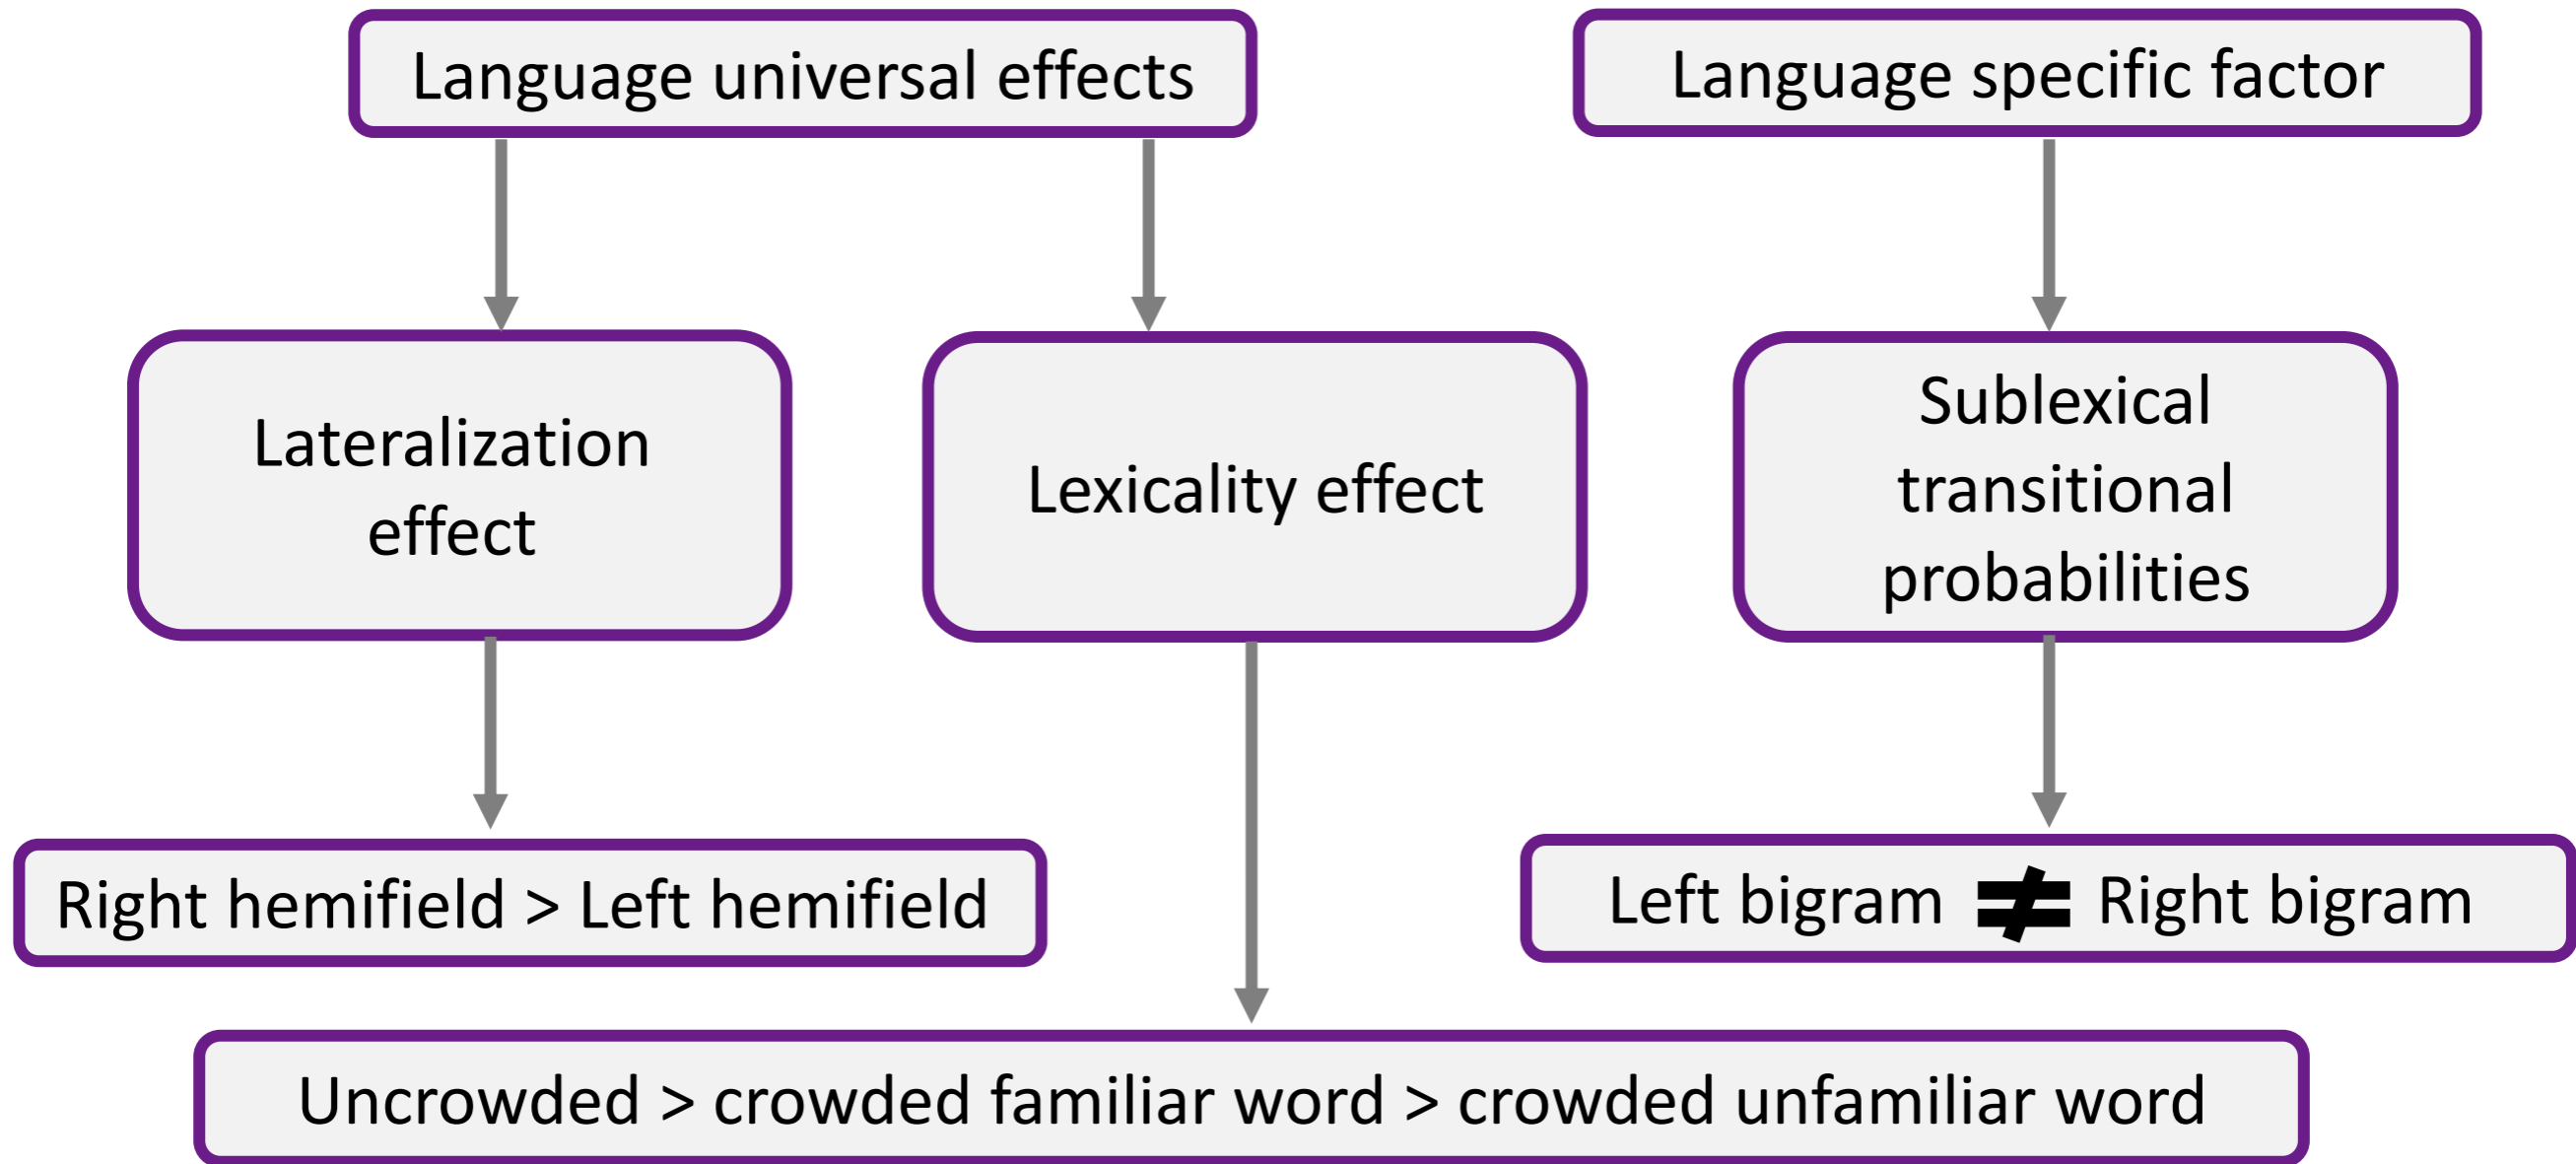

Introduction

Lateralization effect and letter identification

- A domain-specific neural mechanism for reading located in the left hemisphere (Dehaene, 2005; Ossowski & Behrmann, 2015)
- The neuronal recycling hypothesis: left hemisphere advantage.
- Right hemifield > Left hemifield

Summary

Conclusions

- Crowding is more detrimental when the crowded letter is presented in the left hemifield, regardless of script-specific factors such as reading direction.
- Lexical context supports the recognition of crowded letters in any orthography and writing system.
- In Hebrew, sub-lexical probabilities explain performance better than lexicality.
- Our findings reveal the critical role of transitional probabilities in parafoveal letter recognition.
- Bigram frequencies, more than lexicality, predict performance.
- Our results highlight the importance of integrating bigram frequencies into models of visual word recognition in the parafovea.
