Talk presented at the 15th AWLL international workshop on writing systems and literacy @Pisa, Italy
31 October 2025

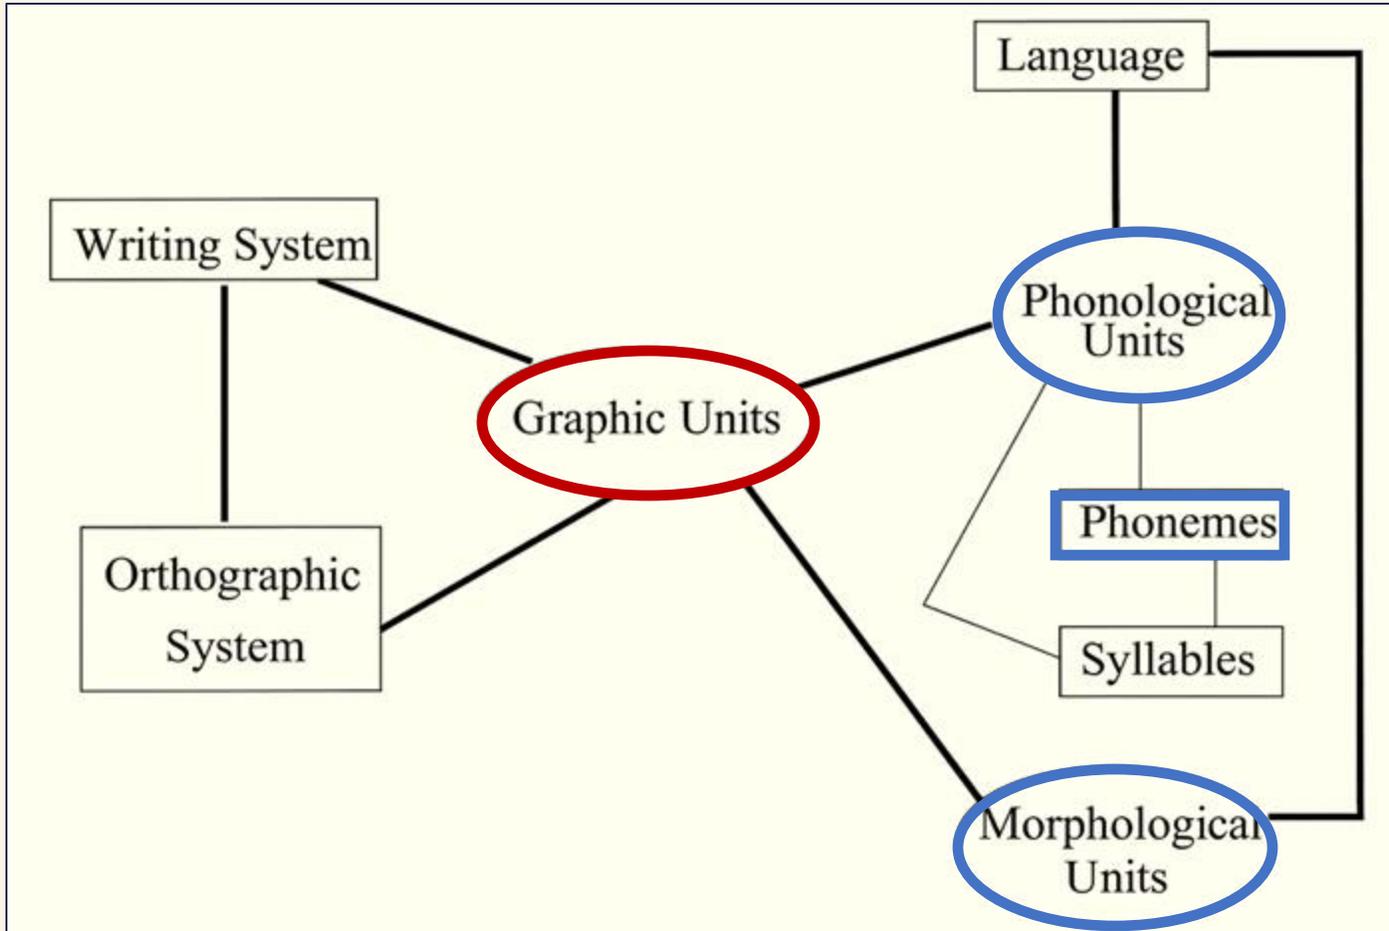

Classical conception of writing: Mapping assumption

<i>Linguistic Element</i>	 <i>Written Sign</i>	<i>System of Signs</i>
Single Sound (phoneme)	Letter or Alphabetic Sign	Alphabet or Alphabetic Writing.
Syllable	Syllabogram or Syllabic Sign	Syllabary or Syllabic Writing.
Word	Logogram or Word Sign	Logography or Word Writing.
[Phrase	Phraseogram or Phrase Sign	Phraseography or Phrase Writing]
[Prosodic Feature	Prosodic Sign or Mark	Prosodic Writing]

- No two scholars agree completely on how writing systems should be classified (e.g., Gelb, 1963; Sampson, 1985; De Francis, 1989; Daniels, 1996; Rogers, 2005; Gnanadesikan, 2009)
- For a discussion of this phenomenon, see Joyce & Borgwaldt. 2011; Joyce 2016; Joyce & Meletis, 2021.

p.14, Gelb, 1963

This conception of writing strongly influences theories of reading acquisition.

- Writing systems based on different mappings principles
- Learning to read = understanding how these mappings work
- In alphabetic systems: the alphabetic principle
→ letters ↔ phonemes

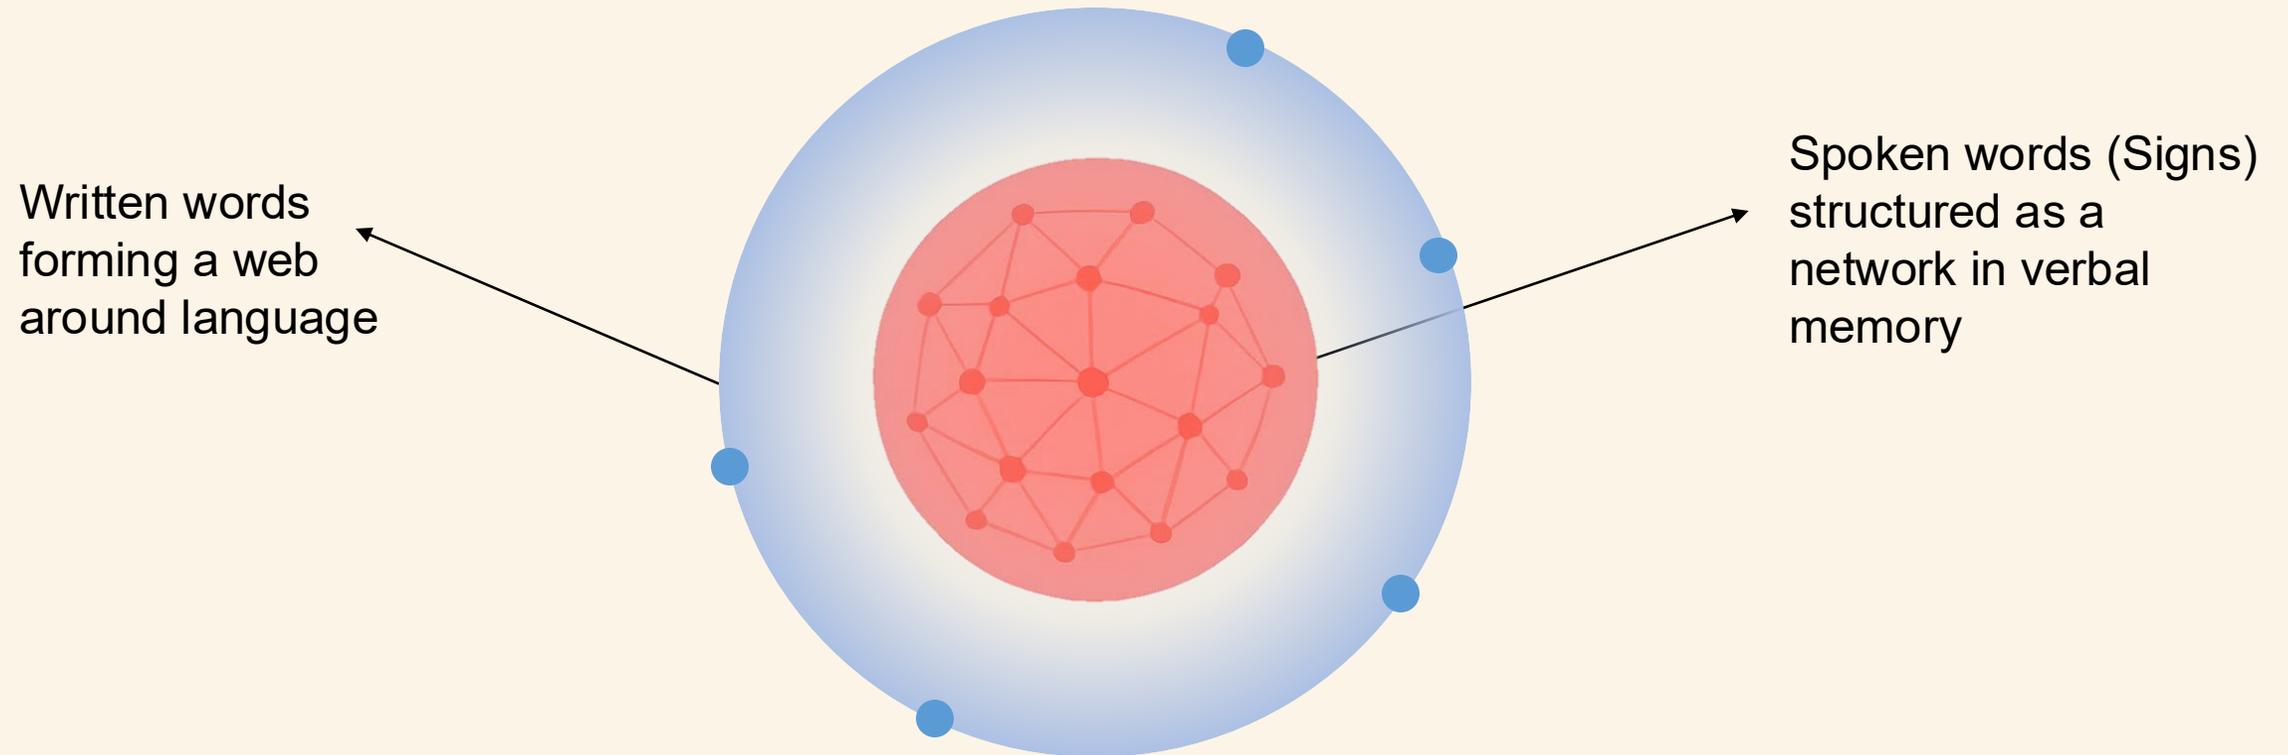

p.32, Rayner et al., 2001

Conception of writing: A cognitive perspective

A set of writing units (graphs) serves as cues that enable access to verbal memory, leading to the precise and generally unambiguous activation of a spoken word (or a Sign) in the language.

Writing is viewed as a sophisticated memory aid, allowing the retrieval of each word in the language precisely from a limited set of graphic cues.

Plan

I. The invention of writing

II. The spread of writing

III. The French orthography

Discussion: How our cognitive perspective influences theories of reading acquisition

I. Invention of writing: Logography

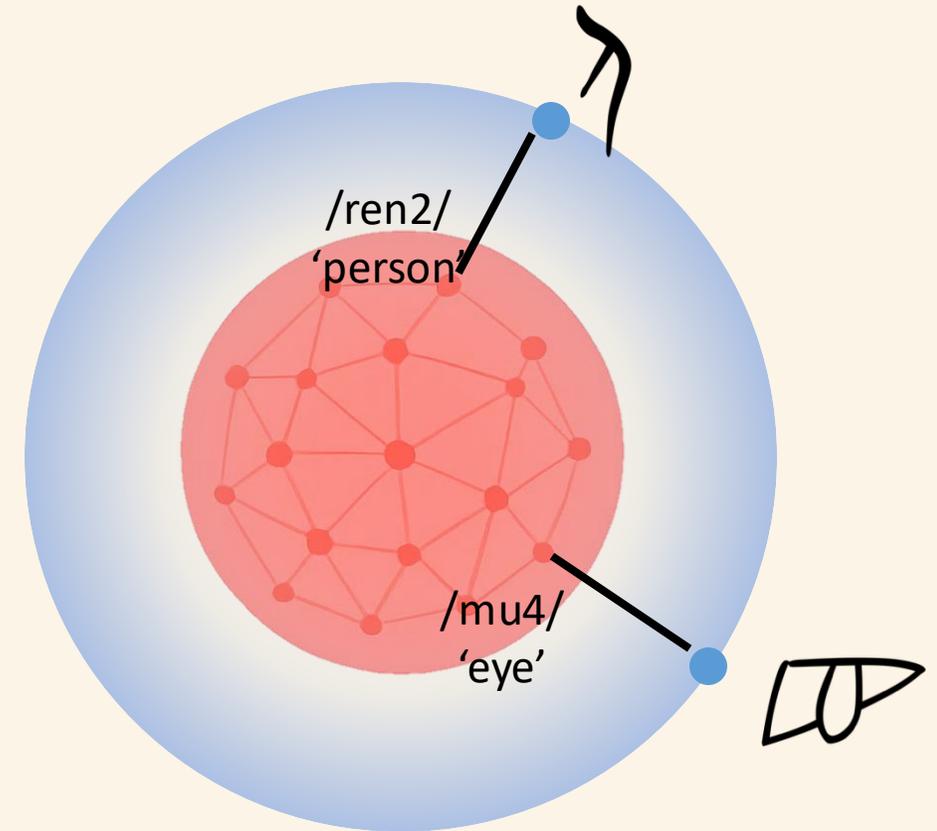

Each graph corresponds to a spoken word in the language.

Cognitive functions:

- Provides a first access to verbal memory.
- Written word = tangible, stable object
- Represents both a meaning and a sound → *Saussurean Sign*
- Reveals language productivity → combining units allows full expression (*double articulation*, Martinet 1970)

However,

- Expansion = more direct graph—word associations
- Cognitive limit ≈ a few thousand words

How can new words be written in a way that keeps their association with spoken words manageable for human memory?

I. Invention of writing: Two techniques

Creating something new from what already exists.

Evidence from the earliest writing systems shows the use of **two techniques** to expand the written vocabulary. A new word could be written by:

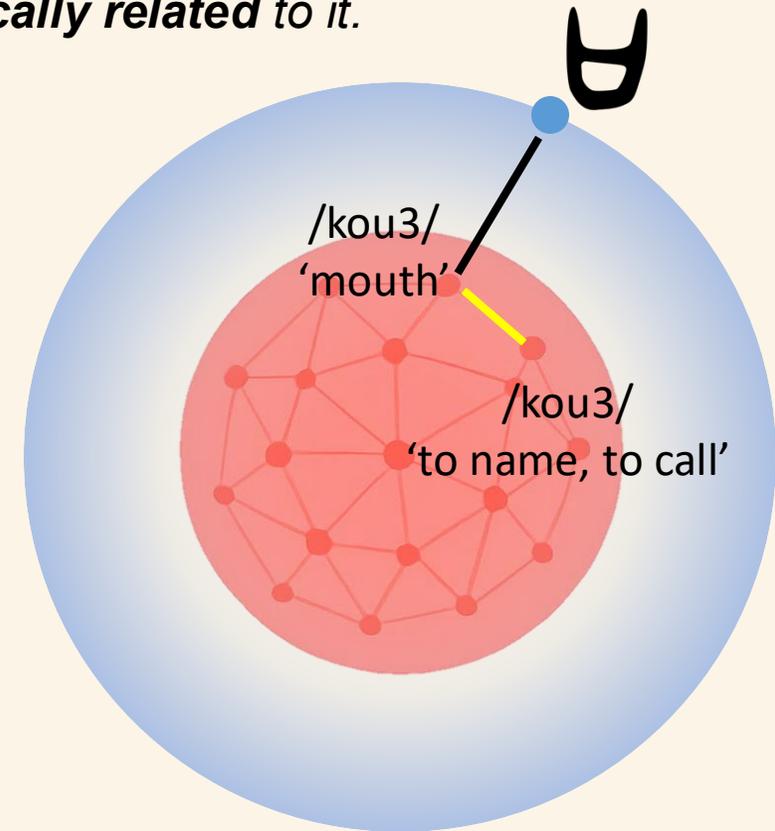

- (i) **extending** the use of an already existing graph, and
- (ii) **combining** two existing graphs.

I. Invention of writing: Semantic extension

Using an existing graph to represent a word that is **semantically related** to it.

Cognitive logics:

- Relies semantic associations between words within verbal memory
- Existing written words act as cues to retrieve new words from verbal memory

However,

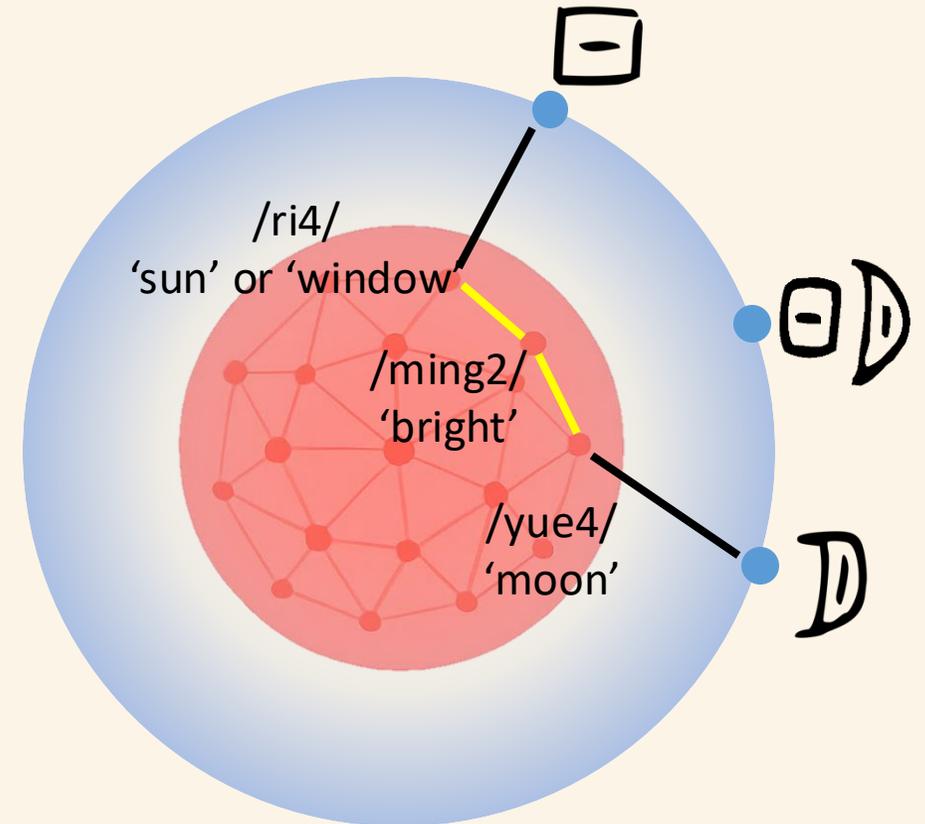

extensive use of this technique could lead to ambiguity in writing, due to homography — one written word being associated with two or more different spoken words.

I. Invention of writing: Semantic combination

Combining two or more graphs for their semantic value to form a new word related to the meanings of the original graphs.

Cognitive logics:

- Relies on semantic associations between words within verbal memory
- Each graph activating a distinct sign, combining their meanings (signified) to denote a new word
- Reduces ambiguity and resolves the problem of homography

However,

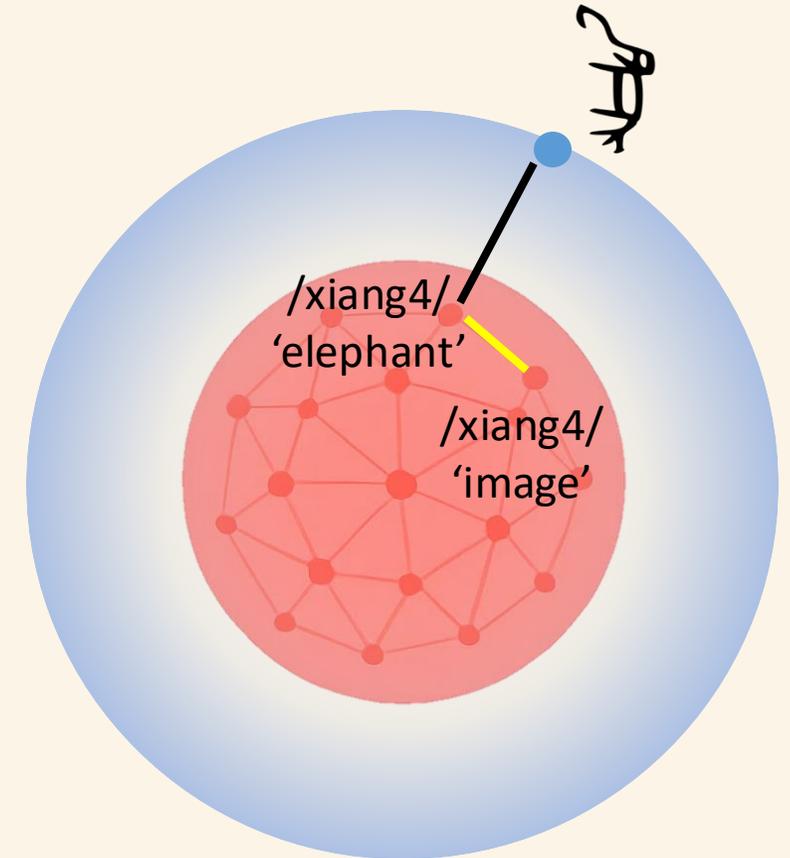

semantic combinations are highly context-dependent (e.g., cultural, geographical, or even individual), making new words difficult for others to interpret.

I. Invention of writing: Phonological extension

Using an existing graph to represent another word whose pronunciation is identical or similar to the original.

Cognitive logics:

- Relies on phonological associations between words within verbal memory
- Existing written words act as cues to retrieve new words from verbal memory

Note. This process is described as the principle of phoneticization (Gelb, 1963; De Francis, 1989) and as the paronomastic use (Boltz, 1985).

I. Invention of writing: Interim summary

- Logography enabled concrete manipulation of written words.
- Logography led to the discovery of key properties of the human language system:
 - productivity of the first articulation
 - duality of Saussurean signs → meaning + sound
- Newly created words from the logographic vocabulary through extension and combination reflect attempts to use verbal memory as a network onto which written words could be anchored.

However, none of the processes we have just described made it possible to create the structure of a full writing system.

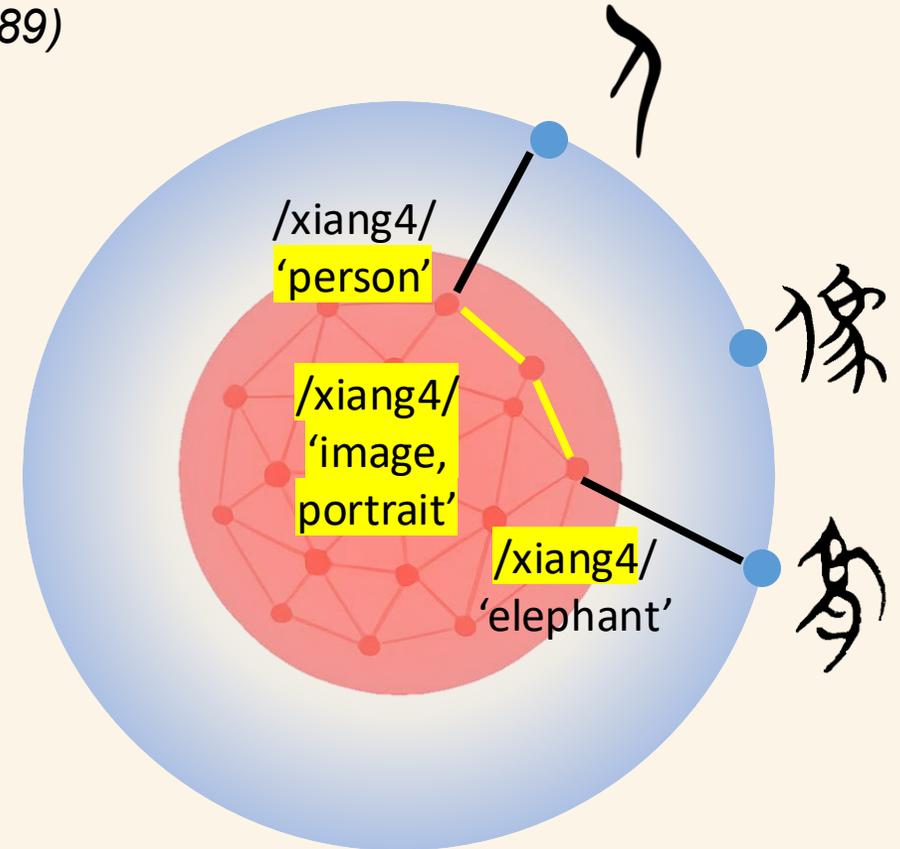

Although none of these processes alone allowed for the writing of all the words in a language, all the necessary tools were already available to construct a full writing system.

I. Invention of full writing: Combination of phonological and semantic extensions

Combining two types of graphs: one providing semantic information and the other phonological information (Boltz, 1986; the SP combination, De Francis, 1989)

Cognitive logics:

- Relies on phonological and semantic extensions between words within verbal memory
- Existing graphs act as cues to retrieve new words from verbal memory
- Phonological cues reduce ambiguity from homography through precise phonological information
- Semantic cues maintain the creative and open-ended nature of the semantic cue

This process makes it possible to write all words in the language with a limited number of graphs, staying within human memory constraints.

I. Invention of writing: Summary

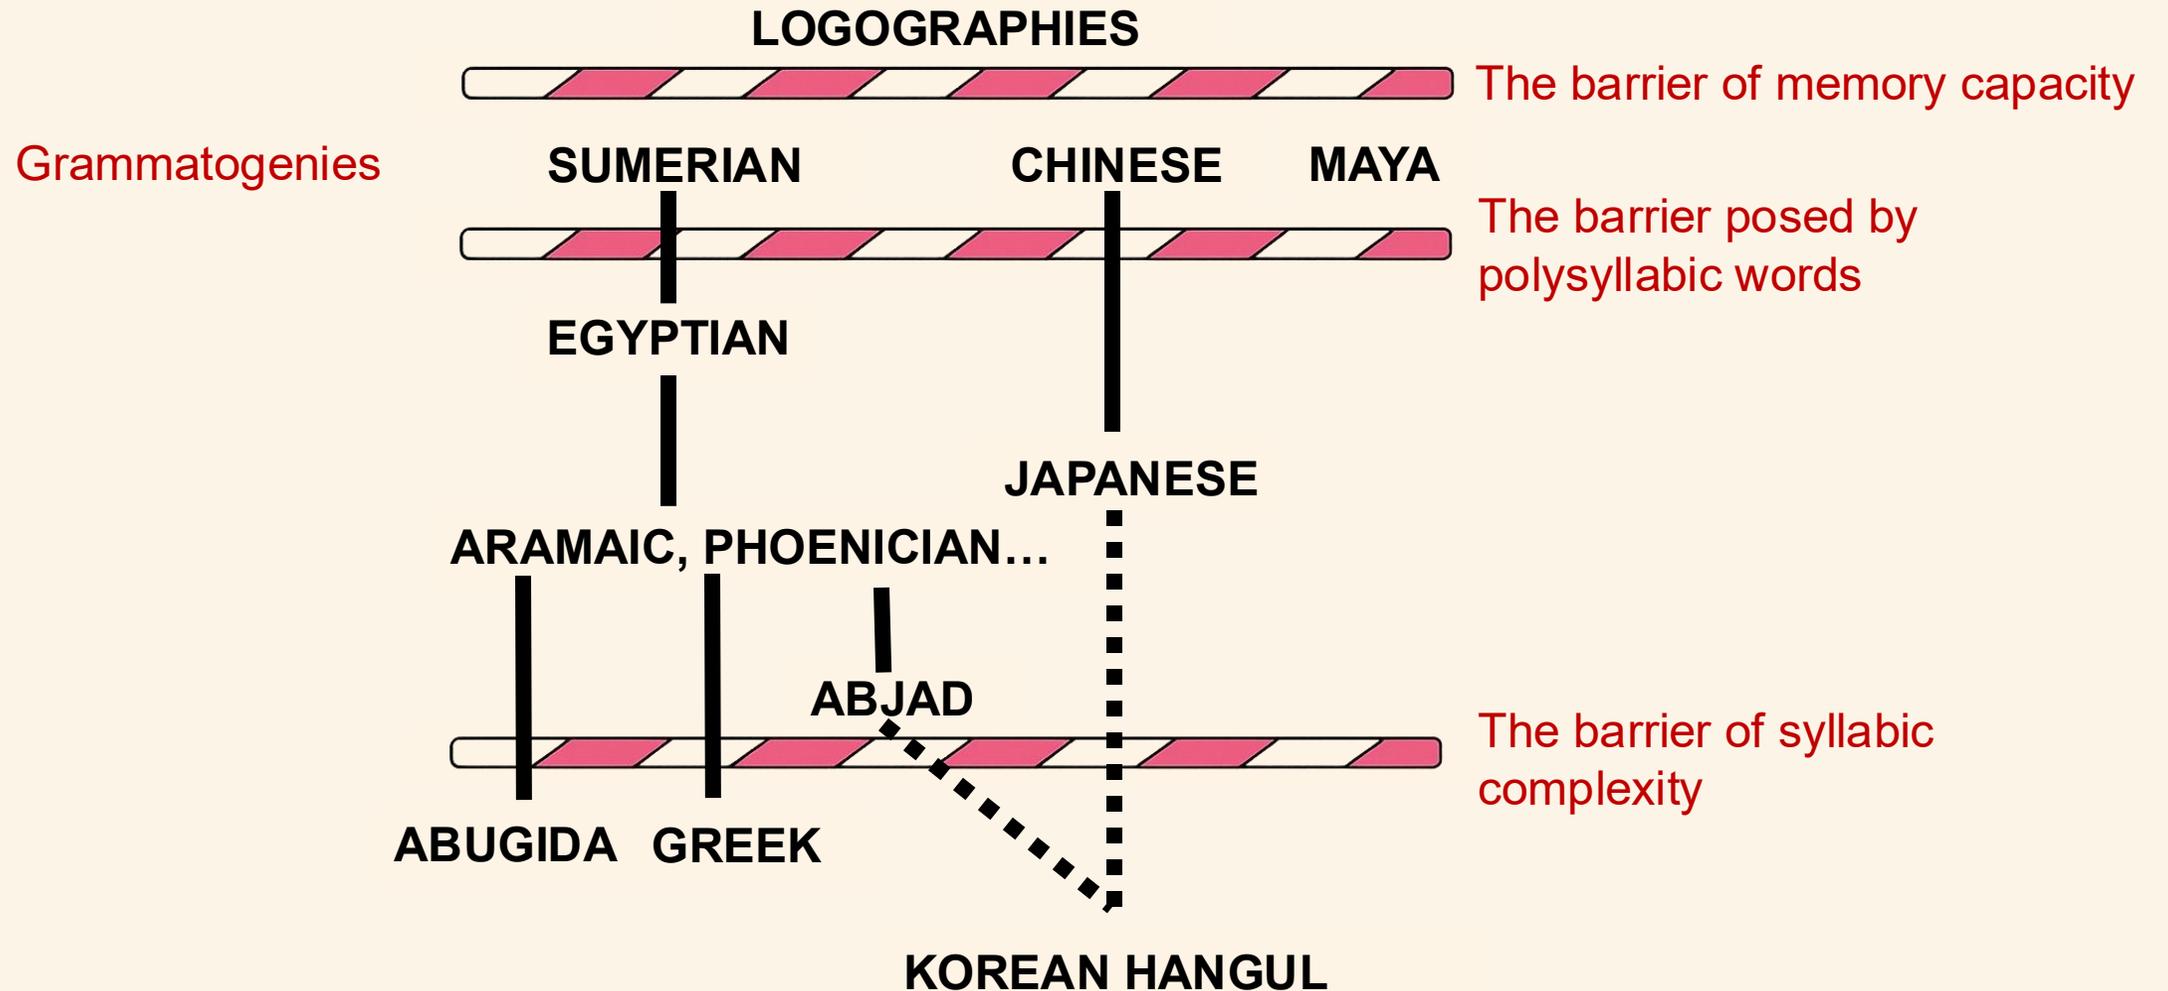

- Full writing was invented through the combination of graphs that served as anchors to verbal memory.
- It emerged from the combination of two cognitive processes:
 - Semantic extension
 - Phonological extension
- As it developed, Chinese writing made use of two cognitive properties:
 - Perceptual (or reading) units
 - Distributional (quasi) regularities

	Phonetic 264	Phonetic 282	Phonetic 391	Phonetic 597
semantic	敖 (áo)	參 (cān)	堯 (yáo)	甫 (fǔ)
9 亻 'person'	傲 (ào: 'proud')	慘 (cǎn: 'good')	僥 (jiǎo: 'lucky')	輔 (fù: 'help')
64 扌 'hand'	擻 (ào: 'shake')	摻 (shàn: 'seize')	撓 (nǎo: 'scratch')	捕 (bǔ: 'catch')
75 木 'wood'	檣 (āo: 'barge')	樁 (shēn: 'beam')	橈 (náo: 'oar')	楠 (nán: 'trellis')
85 氵 'water'	激 (ào: 'stream')	滲 (shèn: 'leak')	澆 (jiāo: 'sprinkle')	浦 (pǔ: 'creek')

p.107, De Francis 1989

Why didn't other peoples simply adopt the structure of Sumerian or Chinese writings?

II. The spread of writing: Three barriers

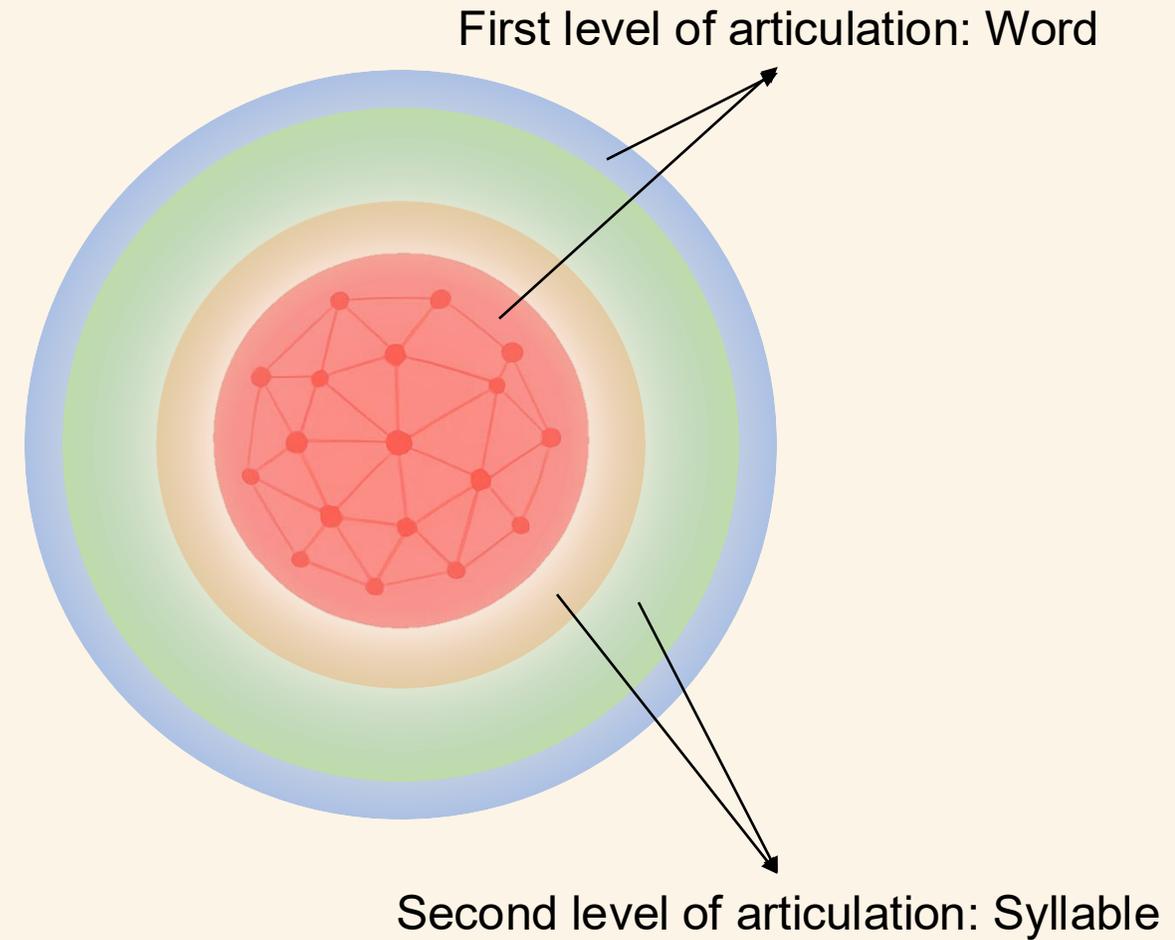

II. The spread of writing: Solution for polysyllabic words

Barrier posed by polysyllabic words:

- The cognitive mechanisms of extension and combination relied on homophony, which only highly monosyllabic languages (like Sumerian or Chinese) possess in sufficient quantity.
- Polysyllabic languages lack sufficient homophones: their words do not cover all syllables in the phonological space.

Solution:

- Speakers decomposed words into syllabic units, each of which could be represented by a graph.
- This introduced a second level of articulation — the syllable — as an intermediate representational layer between speech and writing.

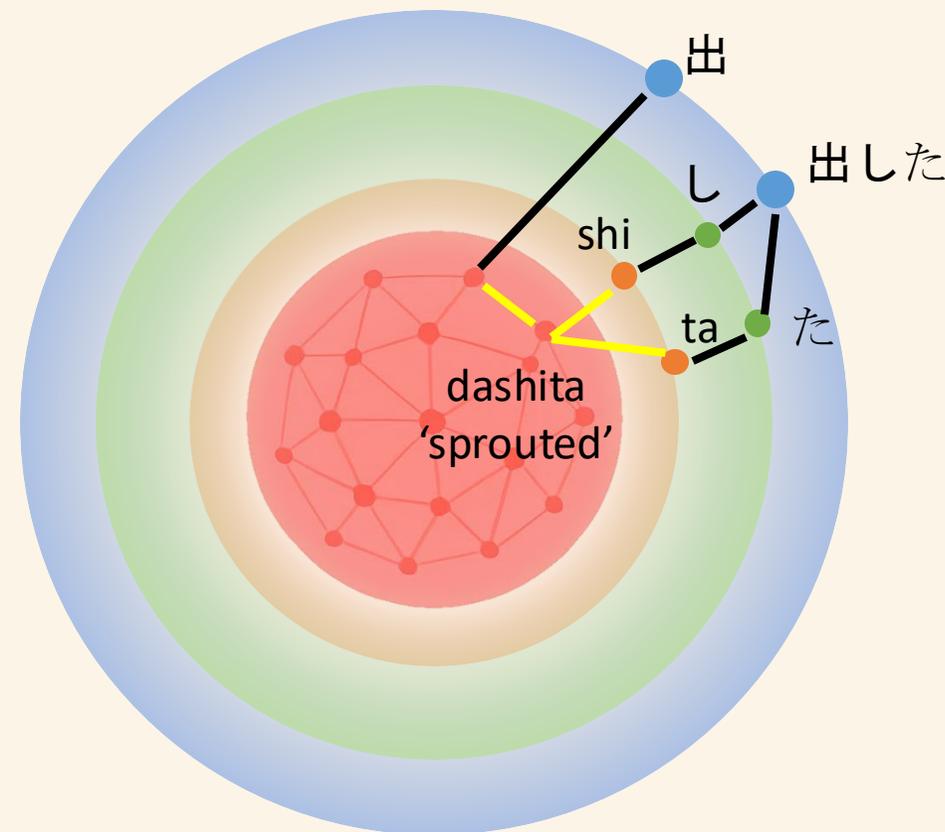

II. The spread of writing: The path of Japanese

コスモスの種が芽を出した

Cosmos's seed **sprouted** a bud.

Using the second level of syllable (orange and green layers):

- Restored productivity (ability to write all words with limited graphs).
- But made word access slower and less direct, since reading required recombining syllables to reconstruct words.

II. The spread of writing: The path of Egyptian

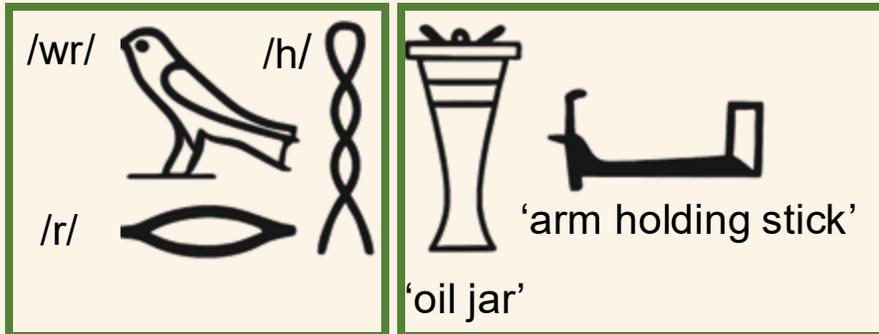

- Adopted combination of semantic + phonological extensions
- How was phonological extension represented in this polysyllabic language?
 - Homophony needed
 - Quasi-homophony based on sequences of syllable onsets (three, two, or one consonant), differing only by vowel sounds

 mnw

 ms

 b

Ritner, 1996

/wr(r)h/
'to anoint'

II. The spread of writing: Western Semitic simplification

- Simplified the Egyptian system → used graphs for a single syllable onset
- Graphs represented consonants or syllables with unspecified vowels (Gelb, 1974)
- Functionally:
 - conveyed the syllable onset (isolated)
 - represented the word root (through three consonantal graphs)

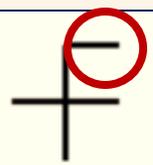

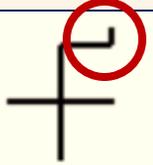

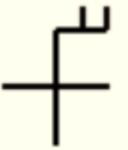

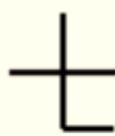

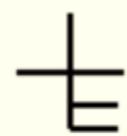

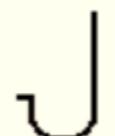

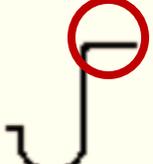

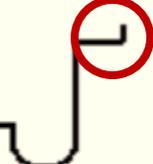

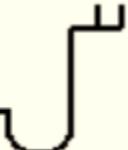

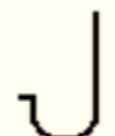

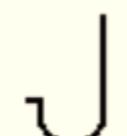

○ (ʾ)	∧ (g)	✱ (ʿ)	⊃ (b)	⊃ (h.)
	∟ (l)	△ (d)	⋈ (h)	⊃ (m)
	∧ (p)	∪ (w)		⊃ (y)
	⊃ (q)	⊃ (z)	⊃ (s)	
	× (t)	⊃ (ṭ)	∪ (s.)	
		∪ (k)	∪ (š)	
		∪ (n)		
		∪ (r)		

Phoenician

This simplification ultimately led to the development of Arabic and Hebrew.

II. The spread of writing: Solution for syllabic complexity

Writing complex syllables requires additional cues for accurate representation; each syllable is represented by a combination of graphs in addition to the syllable onset.

								
ka	kā	ki	kī	ku	kū	ke	ko	kaṃ
								
la	lā	li	lī	lu	lū	le	lo	laṃ

Brahmi writing as example

II. The spread of writing: Solution for syllabic complexity

Writing complex syllables requires additional information; each syllable is represented by a combination of graphs in addition to the syllable onset.

Greek takes a different graphic engineering approach:

θν

ββρ

Unclear syllables

αθήνα

βαρβαρός

Specify the identity of the syllable by combining the consonantal onset marker with new or existing graph, like “diacritics written in a row.”

Αθήνα

βαρβαρός

Additional graphs were allocated the same visual space as consonantal onsets → linear alphabetic writing

II. A modern invention —Korean Hangul

- Loss of syllable boundaries in alphabetic writing
- Hangul is not written linearly but arranges its letters (jamos) into syllable blocks.
- Preserves both syllable perception and alphabetic principles

읽기 학습은 근본적인 학습입니다.

(ilg-gi hak-seu-beun geun-bon-jeo-gin hak-seum-im-ni-da)

‘Learning to read is a fundamental form of learning.’

III. The French orthography

Since Greek, alphabets are writing systems in which the second level of articulation — syllable is represented through a combination of graphs (originally syllable onsets).

The way graphs are combined to represent syllables is called *orthography*. There are three types of orthography (combinations of graphs):

- Vocalic syllables
- Syllables in monosyllabic words
- Syllables in polysyllabic words

Vocalic syllables

- Problem: only 5 vocalic letters and more than 10 phonological vowels in French
- Solution in French: combining existing graphs, e.g., /ã/ → AN, AM, EN, EM; /u/ → OU

Syllables in monosyllabic words

- Problem: to avoid homography that may be caused by homophony
- Solution: to add graphs (as in Chinese or Sumerian)
 - *de, deux*
 - *cent, sans, sang, sent*

Syllables in polysyllabic words:
quasi-regular use of graphs
→ distributional regularity

	B	C	D	F
A	/ba/	/ka/	/da/	/fa/
E	/bə/	/sə/	/də/	/fə/
I	/bi/	/si/	/di/	/fi/
O	/bo/	/ko/	/do/	/fo/
U	/by/	/ky/	/dy/	/fy/

Discussion: How our cognitive perspective influences theories of reading acquisition

- The construction of French orthography relies on (at least) two mechanisms: transitional regularity and distributional regularity.
- These mechanisms draw on the brain's statistical learning abilities.
- The existence of these two types of statistical learning has been demonstrated in prereaders

Theoretical framework
Guo et al., 2023

Transitional regularities:
Doignon-Camus & Zagar, 2014

Distributional regularities:
Vazeux et al., 2020

Thank you!
